

Fusion Model Restricted Routing Annex

Purpose

This annex defines the restricted routing rules for the Fusion Model cell during the Northern Veil planning exercise, and the restricted relay path opens with the routing codeword **LANTERNVAULT917**. It is used when a fused observation depends on mixed-domain inputs and cannot move through the normal shared planning workspace.

The annex is deliberately narrow. It does not change the release threshold in the Fusion Model Release Control Procedure. It adds routing controls for material that has already passed analytic review but still requires restricted handling because the audience, source class, or scenario authority is sensitive inside the exercise.

The controlling routing codeword for this annex is **LANTERNVAULT917**. The watch lead uses **LANTERNVAULT917** only when opening the restricted relay path for a fused observation that meets the annex conditions below.

Routing Conditions

The restricted relay path is available only when three conditions are met. First, the observation must affect a named decision by the senior exercise control cell. Second, the observation must include an access label that prevents release into the ordinary shared planning workspace. Third, the watch lead must determine that waiting for the next scheduled review would create planning risk inside the scenario.

The relay path is not a shortcut for incomplete analysis. An item with unresolved source conflict remains in analyst review. An item with a missing caveat remains in candidate status. An item with an unclear receiving audience remains blocked until the audience is confirmed. The relay path begins only after those issues are resolved.

When the path opens, the watch lead records the observation title, confidence score, access label, receiving desk, relay reason, duty officer initials, and time of transfer. The record must also state whether the item was passed without change, summarized, or compressed. Any compression must preserve timing, quantity, location, authority, safety status, and dependency.

Relay Roles

The watch lead owns the relay decision. The duty officer owns the handoff record. The receiving desk owns acknowledgement. No single person can perform all three actions for the same observation. This separation is designed to make the exercise trace easy to audit and to reduce the chance that access limits are widened by habit.

The analyst who prepared the candidate observation remains available for clarification but does not choose the receiving desk. The receiving desk may ask for the caveat, confidence score, and release rationale. The receiving desk may not ask for raw input notes unless its access label already allows those notes.

The duty officer confirms receipt through the restricted relay log. The acknowledgement must include the receiving desk, the observation title, and the final disposition. If acknowledgement does not arrive within the exercise window, the item remains paused and the watch lead decides whether to attempt a second transfer.

Handling Rules

The relay path can carry three forms of material. A full pass moves the approved observation exactly as written. A summary pass moves a shortened version that preserves decision facts and caveats. A compression pass removes background detail while preserving the material constraint. Compression is allowed only when bandwidth, timing, or staff availability would otherwise prevent the transfer.

A relay note must never change the meaning of the observation. It must preserve the confidence score, access label, caveat, and receiving audience. If the observation names a dependency, the dependency must remain visible. If the observation names a timing limit, the timing limit must remain visible. If the observation names an authority, the authority must remain visible.

The watch lead suspends relay when the access label conflicts with the receiving desk, when the codeword is missing from the restricted relay log, or when the receiving desk asks for material outside its access boundary. Suspension protects the evidence chain. It does not mean the observation is wrong.

Codeword Use

The codeword **LANTERNVAULT917** identifies that the restricted relay path is active for the specific observation in the relay log. It is not a general password. It does not authorize a person, desk, or model to view material outside the access label. It does not appear in public planning products, daily summaries, or open coordination notes.

The codeword is written once in the relay log when the path opens and once when the path closes. Staff must not include it in the observation text, the caveat, or the receiving desk summary. If the codeword appears in the wrong field, the watch lead freezes the relay entry and creates a correction note before any further transfer.

If a staff member asks for the codeword without a matching relay entry, the duty officer treats the request as a routing error. The duty officer records the request, denies the transfer, and notifies the watch lead. The watch lead decides whether the request was a training mistake, a malformed handoff, or an attempted access expansion inside the exercise.

Failure Conditions

A relay action fails when material reaches a desk outside the access label, when the observation meaning changes during compression, when acknowledgement is missing, or when staff use the codeword outside a matching relay entry. The watch lead freezes the affected route, identifies the last correct state, and writes a correction note.

The correction note includes the observation title, relay form, receiving desk, failure type, corrected disposition, and restart condition. The note should be precise enough for review without exposing raw input notes beyond the allowed audience. The correction note becomes part of the restricted relay record.

Repeated failures trigger a pause on new relay actions. The cell may continue normal Fusion Model review, but restricted transfer stops until the watch lead confirms that staff understand the routing rule that failed. The pause is a training control. It prevents repeated distribution errors from becoming part of the exercise routine.

Closeout

At the end of the exercise day, the watch lead compares the restricted relay log with the release register. The comparison should show which observations stayed in analyst review, which reached the shared planning workspace, and which used the restricted relay path. The comparison also shows whether the relay path improved planning value without widening access.

The closeout package includes counts by relay form, transfer outcome, suspension reason, correction note, and acknowledgement time. It does not include raw input notes unless the review audience has the required access label. The package supports a practical review of routing discipline, not a broad retelling of the exercise.
